Maximize Area Between Two Boundaries

Practice Part A - Problem 5 | Python

```
Task: Maximize min(heights[left], heights[right]) * (right-left).
Move the pointer at the shorter wall because the shorter wall limits height.
def maxContainerArea(heights):
left, right = 0, len(heights) - 1
best = 0
while left < right:
height = min(heights[left], heights[right])
best = max(best, height * (right-left))
if heights[left] <= heights[right]:
left += 1
else:
right -= 1
return best

print(maxContainerArea([1,8,6,2,5,4,8,3,7]))

Output: 49
Brute force is O(n^2) time. Two pointers are O(n) time and O(1) extra space.
The linear method scales much better for very large arrays.
```
